All this material is a free re-arrangement of David Silver's UCL Course on RL. You are also encouraged to take a look to his Youtube lectures.

What is reinforcement learning?

### **Branches of Machine Learning**

#### **RL Characteristics**

What makes reinforcement learning different from other machine learning paradigms?

- There is no supervisor, only a *reward* signal.
- Feedback is delayed, not instantaneous
- Time really matters (sequential, non i.i.d. data)
- Agent is *active*: its actions affect the environment he lives in.

#### Rewards

- A reward  $R_t$  is a scalar feedback signal
- ullet Indicates how well agent is doing at step t
- The agent's job is to maximise cumulative reward over an episode

#### Rewards: examples

- Fly stunt manoeuvres in a helicopter
  - +ve reward for following desired trajectory
  - -ve reward for crashing
- Defeat the world champion at Go
  - +ve/-ve reward for winning/losing a game
- Make a humanoid robot walk
  - +ve reward for forward motion
  - -ve reward for falling over
- Play Atari games better than humans
  - +ve reward for increasing/decreasing score

Inside a RL agent

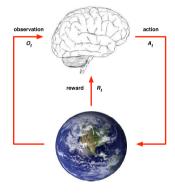

## **Sequential Decision Making**

- Goal: select actions to maximise total future reward
- Actions may have long term consequences
- Reward may be delayed
- It may be better to sacrifice immediate reward to gain more long-term reward.
  - A financial investment may take months to mature
  - Refuelling a helicopter now might prevent a crash in several hours
  - Blocking opponent moves might help winning chances many moves from now

#### Agent and environment

- At each step *t* the agent:
  - ullet Receives observation  $O_t$
  - Receives scalar reward R<sub>t</sub>
  - Executes action A<sub>t</sub>
- The environment:
  - Receives action At
  - Emits observation  $O_{t+1}$
  - Emits scalar reward  $R_{t+1}$
- t increments at env. step

• The history is the sequence of observations, actions, rewards

$$H_t = O_1, R_1, A_1, \dots, A_{t-1}, O_t, R_t$$

- The state is the information used to determine what happens next.
  - It is a function of the history:

$$S_t = f(H_t)$$

#### Agent and environment states

Agent state  $S_t^a$ 

whatever information the agent uses to pick the next action

it is the information used by RL algorithms

Environment state  $S_t^e$ 

whatever data the environment uses to pick the next observation/reward

usually not visible by the agent

- Full observability: agent directly observes environment state
- Partial observability: agent indirectly observes environment state

## Inside a reinforcement learning agent

- An agent may include one or more of these components:
  - Policy: agent's behaviour function
  - Value function: how good is each state and/or action
  - Model: representation of the environment

# **Policy**

- A policy is the agent's behaviour
- It is a map from state to action
- Deterministic policy:  $a = \pi(s)$
- Stochastic policy:  $\pi(a|s) = \mathbb{P}[A_t = s | S_t = s]$

#### **Value function**

- Value function is a prediction of future reward
- Used to evaluate goodness/badness of states
- And therefore to select between actions

$$v_{\pi}(s) = \mathbb{E}_{\pi}[R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots | S_t = s]$$

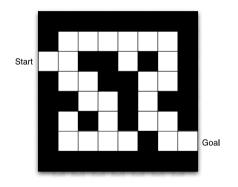

- A model predicts what the environment will do next
- ullet  ${\cal P}$  predicts the next state
- ullet  $\mathcal R$  predicts the next (immediate) reward

$$\mathcal{P}^{a}ss' = \mathbb{P}[S_{t+1} = s'|S_t = s, A_t = a]$$
  
 $\mathcal{R}^{a}_{s} = \mathbb{E}[R_{t+1}|S_t = s, A_t = a]$ 

## Maze example

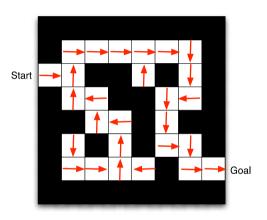

- Rewards: -1 per time-step
- Actions: N, S, W, E
- States: Agent's location

## Maze example: policy

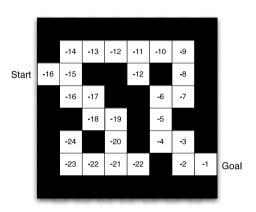

ullet Arrows represent policy  $\pi(s)$  for each state s

### Maze example: value function

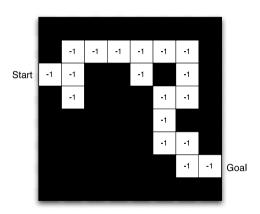

• Numbers represent policy  $v_{\pi}(s)$  for each state s

#### Maze example: model

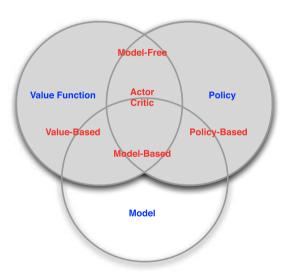

- ullet Grid layout represent transition model  $\mathcal{P}^a_{ss'}$
- Numbers represent immediate reward  $R_s^a$  from each state s (same for all a)

#### **RL** taxonomy

Model-free prediction

### Model-Free prediction

- Model-free prediction
  - estimate the value function given a policy in a non-observable environment
    - Monte-Carlo Learning
    - Temporal-Difference Learning

## Monte-Carlo reinforcement learning

- MC methods learn directly from episodes of experience
- MC is model-free: no explicit knowledge of environment mechanisms
- MC learns from complete episodes
  - Caveat: can only apply to *episodic* environments (all episodes must terminate).
- MC uses the simpliest possible idea: value = mean return

## **Monte-Carlo Policy Evaluation**

• Goal: learn  $v_{\pi}$  from episodes of experience under policy  $\pi$ 

$$S_1, A_1, R_2, \ldots, S_k \sim \pi$$

• Recall that the *return* is the total discounted reward:

$$G_t = R_{t+1} + \lambda R_{t+2} + \ldots + \lambda^{T-1} R_T$$

• Recall that the value function is the expected return:

$$v_{\pi} = \mathbb{E}_{\pi}[G_t|S_t = s]$$

 Monte-Carlo policy evaluation uses empirical mean return instead of expected return

# **Every-Visit Monte-Carlo Policy Evaluation**

- To evaluate state s
- Every time-step t that state s is visited in an episode,
- Increment counter  $N(s) \leftarrow N(s) + 1$
- Increment total return  $S(s) \leftarrow S(s) + Gt$
- Value is estimated by mean return V(s) = S(s)/N(s)
- ullet By law of large numbers,  $V(s) 
  ightarrow v_\pi(s)$  as  $N(s) 
  ightarrow \infty$

### **Incremental Monte-Carlo Updates**

- Update V(s) incrementally after episode  $S_1, A_1, R_2, ..., S_T$
- Compute return  $G_t$
- For each state  $S_t$  with return  $G_t$

$$egin{aligned} \mathcal{N}(S_t) \leftarrow \mathcal{N}(S_t) + 1 \ V(S_t) \leftarrow V(S_t) + rac{1}{\mathcal{N}(S_t)} (G_t - V(S_t)) \end{aligned}$$

• Usually a running mean is employed, i.e. forget old episodes

$$V(S_t) \leftarrow V(S_t) + \alpha(G_t - V(S_t))$$

# Blackjack Example

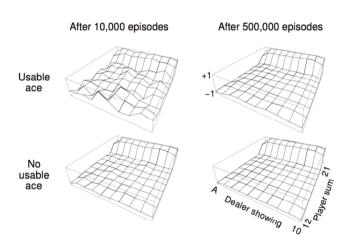

- States (200 of them):
  - Current sum (12-21)
  - Dealer's showing card (ace-10)
  - Do I have a useable ace? (yes-no)
- Action stick: Stop receiving cards (and terminate)
- Action twist: Take another card (no replacement)
- Reward for stick:
  - +1 if sum of cards > sum of dealer cards
  - 0 if sum of cards = sum of dealer cards
  - -1 if sum of cards < sum of dealer cards
- Reward for twist:
  - -1 if sum of cards > 21 (and terminate)
  - 0 otherwise
- Transitions: automatically twist if sum of cards < 12

## Blackjack Value Function after Monte-Carlo Learning

Policy: stick if sum of cards ≤20, otherwise twist

#### MC and TD

- Goal: learn  $v_{\pi}$  online from experience under policy  $\pi$
- Incremental every-visit Monte-Carlo
  - Update value  $V(S_t)$  toward actual return  $G_t$

$$V(S_t) \leftarrow V(S_t) + \alpha(G_t - V(S_t))$$

- Simplest temporal-difference learning algorithm: TD(0)
  - Update value  $V(S_t)$  toward estimated return  $R_{t+1} + \gamma V(S_{t+1})$

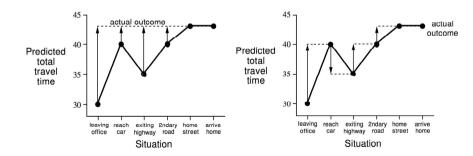

$$V(S_t) \leftarrow V(S_t) + \alpha(R_{t+1} + \gamma V(S_{t+1}) - V(S_t))$$

- $R_{t+1} + \gamma V(S_{t+1})$  is called the TD target
- $\delta_t = R_{t+1} + \gamma V(S_{t+1}) V(S_t)$  is called the TD error

Changes recommended by Monte Carlo methods ( $\alpha$ =1)

Changes recommended by TD methods ( $\alpha$ =1)

## Advantages and disadvantages of MC vs. TD

- TD can learn before knowing the final outcome
  - TD can learn online after every step
  - MC must wait until end of episode before return is known
- TD can learn without the final outcome
  - TD can learn from incomplete sequences
  - MC can only learn from complete sequences
  - TD works in continuing (non-terminating) environments
  - MC only works for episodic (terminating) environments

## Bias/variance trade-off

- Return  $G_t = R_{t+1} + R_{t+2} + \ldots + \gamma^{T-1}R_T$  is unbiased estimate of  $v_{\pi}(S_t)$
- ullet True TD target  $R_{t+1} + v_\pi(S_{t+1})$  is unbiased estimate of  $v_\pi(S_t)$
- TD target  $R_{t+1} + v(S_{t+1})$  is biased estimate of  $v_{\pi}(S_t)$
- TD target is much lower variance than the return:
  - Return depends on many random actions, transitions, rewards
  - TD target depends on one random action, transition, reward

# Model-free control

#### Model-Free control

- Model-free prediction
  - estimate the value function given a policy in a non-observable environment
    - Monte-Carlo Learning
    - Temporal-Difference Learning
- Model-free control
  - find a good policy in a non-observable environment
    - On-Policy Monte-Carlo Control
    - On-Policy Temporal-Difference Learning
    - Off-Policy Learning

## How to improve a policy

- ullet Given a policy  $\pi$
- Evaluate the policy  $\pi$

$$v_{\pi}(s) = \mathbb{E}[R_{t+1} + \gamma R_{t+2} + \dots | S_t = s]$$
  
 $q_{\pi}(s, a) = \mathbb{E}[R_{t+1} + \gamma R_{t+2} + \dots | S_t = s, A_t = a]$ 

ullet Improve the policy by acting greedily with respect to  $v_\pi$ 

$$\pi' = \mathsf{greedy}(v_\pi) \ \pi' = \mathsf{greedy}(q_\pi)$$

- In general, need more iterations of improvement / evaluation
- In model-free contexts, action-value function Q(s, a) is our only option

## **Example of greedy action selection**

"Behind one door is tenure - behind the other is flipping burgers at McDonald's."

Copyright © 2003 David Farley, d-farley@ibiblio.org

- There are two doors in front of you.
- You open the left door and get reward 0 V(left) = 0
- You open the right door and get reward +1V(right) = +1
- You open the right door and get reward +3V(right) = +2
- You open the right door and get reward +2V(right) = +2

• Are you sure you've chosen the best door?

## $\epsilon\text{-greedy exploration}$

- Simplest idea for ensuring continual exploration
- All m actions are tried with non-zero probability
- $\bullet$  With probability  $1-\epsilon$  choose the greedy action
- ullet With probability  $\epsilon$  choose an action at random

$$\pi(a|s) = egin{cases} \epsilon/m + 1 - \epsilon, & ext{if } a^* = rg \max_{a \in \mathcal{A}} Q(s,a) \ \epsilon/m, & ext{otherwise} \end{cases}$$

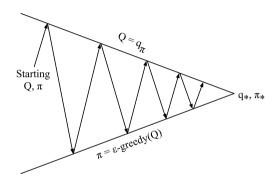

# On and off policy learning

- On-policy learning
  - "Learn on the job"
  - $\bullet$  Learn about policy  $\pi$  from experience sampled from  $\pi$
- Off-policy learning
  - "Look over someone's shoulder"
  - $\bullet$  Learn about policy  $\pi$  from experience sampled from  $\mu$

## Monte-Carlo policy iteration

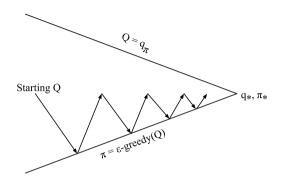

Policy evaluation Monte-Carlo policy evaluation,  $Q=q_\pi$  Policy improvement  $\epsilon$ -greedy policy improvement

### Monte-Carlo control

### Every episode:

Policy evaluation Monte-Carlo policy evaluation,  $Q=q_{\pi}$ Policy improvement  $\epsilon$ -greedy policy improvement

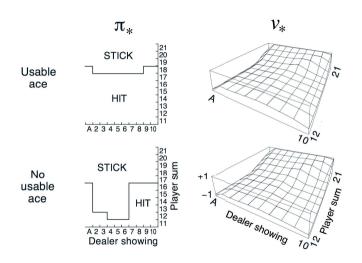

# Back to the blackjack example

### Monte-Carlo control in blackjack

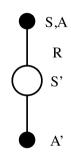

#### MC vs TD control

- Temporal-difference (TD) learning has several advantages over Monte-Carlo (MC)
  - Lower variance
  - Online
  - Incomplete sequences
- Natural idea: use TD instead of MC in our control loop
  - Apply TD to Q(S, A)
  - Use  $\epsilon$ -greedy policy improvement
  - Update every time-step

## Updating action-value functions with SARSA

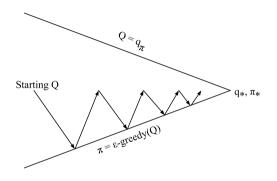

$$Q(S,A) \leftarrow Q(S,A) + \alpha(R + \gamma(Q(S',A') - Q(S,A)))$$

## On-policy control with SARSA

### Every time-step:

Policy evaluation with Sarsa,  $Q pprox q_{\pi}$ 

Policy improvement with  $\epsilon$ -greedy policy improvement.

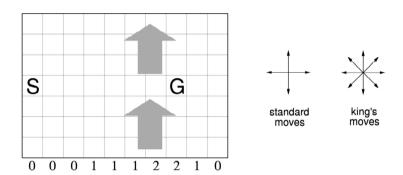

### SARSA algorithm for on-policy control

```
Initialize Q(s, a), \forall s \in S, a \in A(s), arbitrarily, and Q(terminal - state, ) = 0
for each episode do
  Intialise S
  Choose A from S using policy derived from Q (e.g., \epsilon-greedy)
  for each step of episode do
     Take action A. observe R. S'
     Choose A' from S' using policy derived from Q (e.g., \epsilon-greedy)
     Q(S,A) \leftarrow Q(S,A) + \alpha(R + \gamma(Q(S',A') - Q(S,A))
     S \leftarrow S' \cdot A \leftarrow A'
  end for
end for
```

# Windy gridworld example

- ullet Reward = -1 per time step until reaching goal
- Undiscounted

## SARSA on the Windy Gridworld
